Field of the Invention This invention relates generally to the field of virtual machine monitoring and more particularly to the use of SD cards to track the load and/or configuration of a virtual machine. 2. Description of the Related Art When designing an operating system, there are many questions that must be answered. For example, it is important to know how many virtual machines there will be and what type of usage they will have. Further, it is important to know how much memory will be needed and how much disk space will be available. If the number of virtual machines is quite large and/or the type of usage is not known in advance, it is usually not practical to build the operating system in advance, but rather, design the operating system on the fly. For example, see U.S. Pat. No. 6,058,037, which discloses an operating system designed on the fly using code written in a "bytecode" language. Bytecode is a programming language that typically is executed by a special interpreter program. Bytecode is a sequence of instructions for a virtual machine that are stored in variable-sized fields (or slots) defined by the bytecode itself. The bytecode is processed by the interpreter as described above. Bytecode is also used to customize the operation of the operating system. A bytecode of a virtual machine is executed, thereby changing the operation of the virtual machine. For example, bytecode is used to reload a configuration file into the virtual machine. The operating system described in U.S. Pat. No. 6,058,037 is commonly referred to as a live-bytecode virtual machine. A live-bytecode virtual machine may be used to implement any of a variety of live-bytecode virtual machine monitoring (LVM). For example, a live-bytecode virtual machine monitor may be used to monitor
