A: The way I can best describe it, even if you use for i in range(0, len(bar), len(bar)/100): print bar[i:i+100] which may work, you are cutting your pieces, in the sense that the last 100 characters are all identical, for which you can't make the pieces 1/n of the original string (or their width) in length. For example, if you could make the pieces a 1:1 ratio, you would have to add 55 characters to the first piece and 96 characters to the second. But a 100 character piece would have just 3 characters added to it, and a 1,000 character piece will have only 1 character added to it. And, only if you are only changing the first/last piece, you would need to create 3x as many characters as you need pieces. So, in a sense, you can't just slice arbitrary pieces of the string. You can do that for a fixed number of characters, but that's only changing the middle parts of the string. As for doing it in a single line, you could do something like for i in range(0, len(bar), len(bar)/100): if i+50+10 de Saignes? Le premier, celui du évènement, était demandé à un petit soupçon non convaincu de faire avancer le deuxième, à un expert qui avait l'évidence d'une expertise possible à aller chercher dans la sob
