For example, the key string "Android" has 7 characters, but the driver has to find all keys and perform matching of every string. I'll be using plain strings to search the dll file for the key string and then return the class pointer in a temporary class pointer variable. I then increment the variable by the length of the key string. Then I call a function which uses that temporary class pointer and searches the driver for the key and returns the data for that key in a temporary array. I don't think so.. I am not sure but I think the api for use in c++ is not the same like the c api used in c#. I see you found the correct code.. As I said in the other question I found the code for the driver in c++ and converted it to c#. I am not sure if this driver is free to use. You need to pay for the driver.. If the driver is available for free then you should post it here so other people can use it. The user required a driver that enables him to read bar codes in terminal. But the driver he found is not free. He posted the driver in the question. My point was that he should post the driver here. Thanks for the explanation. Well you can put the driver in your project. The dll is in the project. That means it was in your program when it was working. When the old program was deleted or closed you cannot edit it. You must put the dll in the project again. You have to say where the dll is in the project. If you do not put it in the project it cannot be changed. You need to put it in the project that you opened again. Or you can manually open the project that you closed. If you do this then the user in the other question must post the driver here. I found a library for the driver.. It is in the old question of the user. I just converted it to c#. I had already posted it in the old question. Since I posted the dll, it is no longer necessary for the other user to post the driver here. You cannot always get the correct answer just by opening a question. I have two terminals and two projects.
