I'll restate it here: Theorem: Let X be a locally compact Hausdorff space and let $Y \subseteq X$ be open. Let K be an arbitrary compact set of X . Then there exists an open set $U \subseteq Y$ such that $K \subseteq U$ and $U \cap K^c = \emptyset$. Proof: Let K be compact and let K^c be its complement. Then K^c is compact as well, so we can find compact $C \subseteq K^c$ such that $C \cap K^c = \emptyset$. Then $K \cap C = \emptyset$, which is what we want. So far so good. But I really want to be able to understand this. Why does this work? This feels really abstract to me. In a statement like: "Let X be a locally compact Hausdorff space and let $Y \subseteq X$ be open" I feel like I know what I'm supposed to expect, but for this it's just mind-blowing. How does it know that K^c is compact and so can find C ? Is it a general property of locally compact Hausdorff spaces? Why does it work? I'd greatly appreciate it if people could please take the time to thoroughly explain how something like this actually follows from the axioms for locally compact Hausdorff spaces. I'm having a really hard time seeing the details. A: It isn't a property of locally compact Hausdorff spaces. The problem comes from the fact that your statement refers to two things: X is a locally compact Hausdorff space c6a93da74d
