i was installing a new server and during the install, i got an error (error code 0x80070003 and 0x800705b3). when i opened control panel and tried to check for updates, it failed. it appeared to happen multiple times as it would stop and then restart, but each time it failed with a different error code (0x80070003 and 0x800705b3). i have tried multiple repair options in the control panel, clean install and then repair install. all failed with the same error code. i have now turned off my router (off-line) and i can't even update windows update. when i try to update windows update in offline mode, the same error code shows up and the update status is always set to "failed". i have also tried to run "msiexec /i winupdate.msi" in offline mode and the same error code shows up. i have tried all of the standard fixes (registry, windows update service, etc.), but no solution has worked. i have also followed the instructions on the "microsoft support services endpoint" site to no avail. - have uninstalled the "windows 10 fall creators update" update and reinstalled and have uninstalled the update again a few times but have the same problem. can't get past 0% and when i install updates offline, it gives me the same error (0x800705b3 and 0x80070003). this has been since the first time i installed the update a few months ago. i have a dell machine with windows 10 (x64 bit) well, after talking with the its tech support guy (who i thought at first was joking), i thought i would try this, but i was shocked to see this is working. i am glad i did, because it took me a while but then i was able to reinstall the software and i have not had the popup window since. when i tried to update the software before i rebooted, a popup window said "invalid update" and asked me if i wanted to continue. i checked the logs and searched on google and saw several reference to this problem.

temspower requires special hardware, a particular processor and a special bios setting to enable full benchmarking capabilities. for this reason, the software will only run on motherboards equipped with the appropriate hardware. the computer used for the benchmarks must be configured with a pentium d cpu, a cpu with turbo boost feature (intel core 2 duo or amd athlon 64), a gigabyte ga-p35-ds3 motherboard and an nvidia geforce 8800 gt / ati radeon hd3850 discrete graphics card. it also requires a recent operating system and certain drivers. the software does not work in windows vista home premium and windows 8.1. temspower helps you to control your pc temperature. it achieves this by using the sensor located in your cpu. this sensor is powered by two elements: a digital and an analog power supply unit (psu). the software can connect to the cpu on a pci bus, but it cannot access the digital part of the psu. unlike the previous benchmarks, heat it was developed with certain hardware in mind. its first version works on multi-core computers, while version 2.3 now supports both 64-bit and 32-bit editions of windows as well as amd athlon and core i processors. it supports up to four graphics cards with two geforce 8800 gtx / ati radeon hd4850 or two geforce 8800 gts / ati radeon hd3870. the software uses the exact same sensor as temspower, but it communicates with the pc only via a specific usb port. this means that the installation process requires the usb driver and an available free usb port on your pc. temspower is a well-established and well-regarded benchmarking tool. its layout is simple and intuitive to use. the interface is responsive, and the benchmarking results are displayed and updated in real time. it does not require a mouse to use, but you have the option to use one if desired. the benchmark results display the speed and latency of your hard disk, your cpu, your memory, your graphics card and even your usb 3.0 or thunderbolt port. 5ec8ef588b
